**Bio**MIMESYS<sup>®</sup>

### **INCREASED CULTURE TIME**

### INTRODUCTION

BIOMIMESYS<sup>®</sup>*Liver* recreates the complex cellular microenvironment of the liver to extend longevity and functionality of hepatocytes in culture:

- The life of human primary hepatocytes grown in a 2D sandwich is low, 3-10 days (1) and is accompanied by dedifferentiation, leading to the loss of function.
- In 2D culture, HepG2 due their ability to proliferate quickly, reach confluence and have low hepatocyte functions limiting their use for metabolic studies or drug induced liver injury, DILI (2)

Therefore, a culture in BIOMIMESYS<sup>®</sup> Liver:

by

- > Doubles the human primary hepatocytes viability compared to a 2D culture.
- > Allows HepG2 to grow without impairing the viability and morphology for at least 4 weeks.

(1) 3D cultivation techniques for primary human hepatocytes, Bachmann A. et al. Microarrays. 4:64-83, 2015

(2) Comparison of primary human hepatocytes and hepatoma cell line Hepg2 with regard to their biotransformation properties. Wilkening S et al. Drug Metab Dispos. 31:1035-1042, 2003.

### **Materials required**

- ➢ BIOMIMESYS<sup>®</sup>Liver
- > HepG2 from ATCC & cryopreserved primary human hepatocytes
- Live/Dead<sup>®</sup>kit (Life Technologies)
- HCM BulletKit (Lonza)
- Brigthfield Microscope
- Epifluorescence microscope

### Hydroscaffold properties

Translucent and porous

### Method

> Perform Live/Dead<sup>®</sup> test with the kit, following the manufacturer's instructions

# **Bio**MIMESYS®

### RESULTS

HepG2 grown in BIOMIMESYS<sup>®</sup>Liver:

by

HCS Pharma

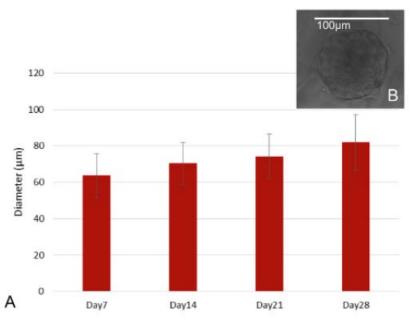

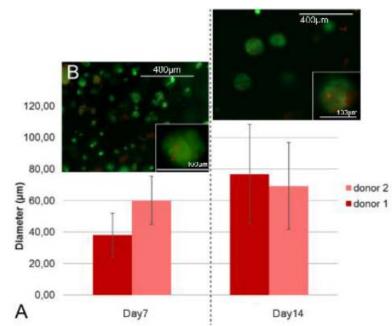

Figure 1: Average size (A) for 28 days (3 independent experiments, n = 70 spheroids measured per experiment) and observation by brightfield microscopy(B) of HepG2 grown in BIOMIMESYS<sup>®</sup>Liver

HepG2 form spheroids with an average diameter of 80-100  $\mu$ m after one month of cultivation.

Cryopreserved human hepatocytes grown within the specific matrix

Figure 2: (A) Average diameter of cryopreserved human hepatocytes cultured in BIOMIMESYS<sup>®</sup>Liver (n ≥25) and (B) observation by fluorescence microscopy highlighting the structure aggregates, at day7 and 14.

## **BioMIMESYS®**

Cryopreserved primary human hepatocytes form small aggregates, 40-80 µm, which have an excellent viability until day14.

### CONCLUSION

The cells exhibit excellent viability during culture time, greater than those achieved in 2D:

arma

- Two weeks for cryopreserved human hepatocytes, hence up to twice more than in 2D culture with the sandwich technique (1).
- ➢ Four weeks for HepG2 cultures.

by

Furthermore, there is no confluence or cellular degeneration problem with the HepG2 cell line in BIOMIMESYS<sup>®</sup>Liver cultures.
